I have reviewed the information you Faxed to me. They are correct in stating that TCA is not a VOC, but I have no record of it being removed from the 112 list of hazardous air pollutant. The latest list I have dated June '01, still list it as a HAP. DCE is not on the HAP list as they state in their letter. As far as the need to control the emissions, I would need to know the TCA potential. They could show that the stack discharge is less than the Department's old Air Toxic limit of 2470 ug/m3. If it is less than 1 ton per year and the DCE has a potential of only 1.9 pounds per year, I would tend to agree with them. The reduction in emissions from the boiler will offset the VOC emission most likely. They would need to monitor the potentials for any changes, but that is unlikely.

If you have any questions, let me know.
